Divide-and-Conquer II Carola Wenk

Slides courtesy of Charles Leiserson with changes and additions by Carola Wenk

Powering a number

Problem: Compute a^n , where $n \in \mathbb{N}$.

Naive algorithm: $\Theta(n)$.

Divide-and-conquer algorithm: (recursive squaring)

$$a^{n} = \begin{cases} a^{n/2} \cdot a^{n/2} & \text{if } n \text{ is even;} \\ a^{(n-1)/2} \cdot a^{(n-1)/2} \cdot a & \text{if } n \text{ is odd.} \end{cases}$$

$$T(n) = T(n/2) + \Theta(1) \implies T(n) = \Theta(\log n)$$
.

Matrix multiplication

Input:
$$A = [a_{ij}], B = [b_{ij}].$$

Output: $C = [c_{ij}] = A \cdot B.$ $i, j = 1, 2, ..., n.$

$$\begin{bmatrix} c_{11} & c_{12} & \cdots & c_{1n} \\ c_{21} & c_{22} & \cdots & c_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ c_{n1} & c_{n2} & \cdots & c_{nn} \end{bmatrix} = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{bmatrix} \cdot \begin{bmatrix} b_{11} & b_{12} & \cdots & b_{1n} \\ b_{21} & b_{22} & \cdots & b_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ b_{n1} & b_{n2} & \cdots & b_{nn} \end{bmatrix}$$

$$c_{ij} = \sum_{k=1}^{n} a_{ik} \cdot b_{kj}$$

Standard algorithm

```
for i \leftarrow 1 to n
do for j \leftarrow 1 to n
do c_{ij} \leftarrow 0
for k \leftarrow 1 to n
do c_{ij} \leftarrow c_{ij} + a_{ik} \cdot b_{kj}

Running time = \Theta(n^3)
```

Divide-and-conquer algorithm

IDEA:

 $n \times n$ matrix = 2×2 matrix of $(n/2) \times (n/2)$ submatrices:

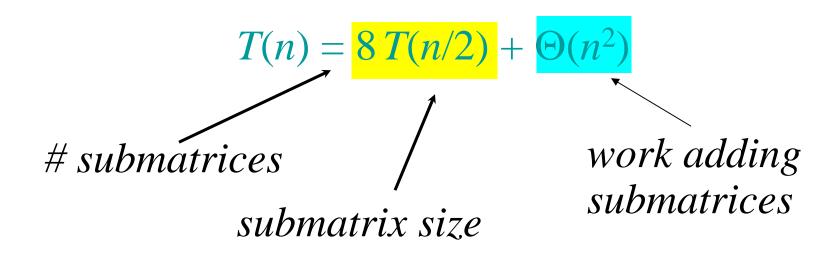

$$\begin{bmatrix} r & s \\ t & u \end{bmatrix} = \begin{bmatrix} a & b \\ c & d \end{bmatrix} \cdot \begin{bmatrix} e & f \\ g & h \end{bmatrix}$$

$$C = A \cdot B$$

$$r = a \cdot e + b \cdot g$$

 $s = a \cdot f + b \cdot h$ 8 recursive mults of $(n/2) \times (n/2)$ submatrices
 $t = c \cdot e + d \cdot g$ 4 adds of $(n/2) \times (n/2)$ submatrices
 $u = c \cdot f + d \cdot h$

Analysis of D&C algorithm

Solves to
$$T(n) = \Theta(n^3) = \Theta(n^{\log 8})$$

No better than the ordinary matrix multiplication algorithm.

Strassen's idea

• Multiply 2×2 matrices with only 7 recursive mults.

$$P_{1} = a \cdot (f - h)$$

$$P_{2} = (a + b) \cdot h$$

$$P_{3} = (c + d) \cdot e$$

$$P_{4} = d \cdot (g - e)$$

$$P_{5} = (a + d) \cdot (e + h)$$

$$P_{6} = (b - d) \cdot (g + h)$$

$$P_{7} = (a - c) \cdot (e + f)$$

$$r = P_5 + P_4 - P_2 + P_6$$

$$s = P_1 + P_2$$

$$t = P_3 + P_4$$

$$u = P_5 + P_1 - P_3 - P_7$$

7 mults, 18 adds/subs.
Note: No reliance on commutativity of mult!

Strassen's idea

• Multiply 2×2 matrices with only 7 recursive mults.

$$P_{1} = a \cdot (f - h) \qquad r = P_{5} + P_{4} - P_{2} + P_{6}$$

$$P_{2} = (a + b) \cdot h \qquad = (a + d)(e + h)$$

$$P_{3} = (c + d) \cdot e \qquad + d(g - e) - (a + b)h$$

$$P_{4} = d \cdot (g - e) \qquad + (b - d)(g + h)$$

$$P_{5} = (a + d) \cdot (e + h) \qquad = ae + ah + de + dh$$

$$P_{6} = (b - d) \cdot (g + h) \qquad + dg - de - ah - bh$$

$$P_{7} = (a - c) \cdot (e + f) \qquad + bg + bh - dg - dh$$

$$= ae + bg$$

Strassen's algorithm

- 1. Divide: Partition A and B into $(n/2)\times(n/2)$ submatrices. Form P-terms to be multiplied using + and -.
- 2. Conquer: Perform 7 multiplications of $(n/2)\times(n/2)$ submatrices recursively.
- 3. Combine: Form C using + and on $(n/2)\times(n/2)$ submatrices.

$$T(n) = 7 T(n/2) + \Theta(n^2)$$

Analysis of Strassen

$$T(n) = 7 T(n/2) + \Theta(n^2)$$

Solves to
$$T(n) = \Theta(n^{\log 7})$$

The number 2.81 may not seem much smaller than 3, but because the difference is in the exponent, the impact on running time is significant. In fact, Strassen's algorithm beats the ordinary algorithm on today's machines for $n \ge 30$ or so.

Best to date (of theoretical interest only): $\Theta(n^{2.376\cdots})$.
