Dynamic tables

**Task:** Store a dynamic set in a table/array. Elements can only be inserted, and all inserted elements are stored in one contiguous part in the array. The table should be as small as possible, but large enough so that it won’t overflow.

**Problem:** We may not know the proper size in advance!

**Solution:** Dynamic tables.

**IDEA:** Whenever the table overflows, “grow” it by allocating (via `malloc` or `new`) a new, larger table. Move all items from the old table into the new one, and free the storage for the old table.

Example of a dynamic table

1. **INSERT**  
2. **INSERT**

Worst-case analysis

Consider a sequence of $n$ insertions. The worst-case time to execute one insertion is $O(n)$. Therefore, the worst-case time for $n$ insertions is $n \cdot O(n) = O(n^2)$.

**WRONG!** In fact, the worst-case cost for $n$ insertions is only $\Theta(n) \ll O(n^2)$.

Let’s see why.

Tighter analysis

Let $c_i =$ the cost of the $i$th insertion

<table>
<thead>
<tr>
<th>$i$</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
<th>8</th>
<th>9</th>
<th>10</th>
</tr>
</thead>
<tbody>
<tr>
<td>$size_i$</td>
<td>1</td>
<td>2</td>
<td>4</td>
<td>4</td>
<td>8</td>
<td>8</td>
<td>8</td>
<td>8</td>
<td>16</td>
<td>16</td>
</tr>
<tr>
<td>$c_i$</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>?</td>
<td>?</td>
</tr>
</tbody>
</table>

Tighter analysis

Let $c_i =$ the cost of the $i$th insertion

$$= 1 + \text{cost to double array size}$$
Tighter analysis

Let \( c_i \) = the cost of the \( i \)th insertion

\[ c_i = 1 + \text{cost to double array size} \]

<table>
<thead>
<tr>
<th>( i )</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
<th>8</th>
<th>9</th>
<th>10</th>
</tr>
</thead>
<tbody>
<tr>
<td>size(_i)</td>
<td>1</td>
<td>2</td>
<td>4</td>
<td>4</td>
<td>8</td>
<td>8</td>
<td>8</td>
<td>16</td>
<td>16</td>
<td>1</td>
</tr>
<tr>
<td>( c_i )</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

3/13/08 CS 5633 Analysis of Algorithms 17

Tighter analysis (continued)

Cost of \( n \) insertions = \[ \sum_{i=1}^{n} c_i \]

\[ \leq 2n + \sum_{j=0}^{\lfloor \log(n-1) \rfloor} n \]

\[ \leq 3n \]

\[ = \Theta(n) \]

Thus, the average cost of each dynamic-table operation is \( \Theta(n)/n = \Theta(1) \).

3/13/08 CS 5633 Analysis of Algorithms 19

Amortized analysis

An amortized analysis is any strategy for analyzing a sequence of operations:

• compute the total cost of the sequence, OR

• amortized cost of an operation = average cost per operation, averaged over the number of operations in the sequence

• amortized cost can be small, even though a single operation within the sequence might be expensive

3/13/08 CS 5633 Analysis of Algorithms 20
Amortized analysis

Even though we’re taking averages, however, probability is not involved!

• An amortized analysis guarantees the average performance of each operation in the worst case.

Types of amortized analyses

Three common amortization arguments:
• the aggregate method,
• the accounting method,
• the potential method.

We’ve just seen an aggregate analysis.

The aggregate method, though simple, lacks the precision of the other two methods. In particular, the accounting and potential methods allow a specific amortized cost to be allocated to each operation.

Accounting method

• Charge $i$th operation a fictitious amortized cost $\hat{c}_i$, where $1$ pays for 1 unit of work (i.e., time).
• This fee is consumed to perform the operation, and any amount not immediately consumed is stored in the bank for use by subsequent operations.
• The bank balance must not go negative! We must ensure that

$$\sum_{i=1}^{n} c_i \leq \sum_{i=1}^{n} \hat{c}_i$$

for all $n$.
• Thus, the total amortized costs provide an upper bound on the total true costs.

Accounting analysis of dynamic tables

Charge an amortized cost of $\hat{c}_i = 3$ for the $i$th insertion.
• $1$ pays for the immediate insertion.
• $2$ is stored for later table doubling.

When the table doubles, $1$ pays to move a recent item, and $1$ pays to move an old item.

Example:

$0 0 0 0 0 3 2 2 2 2 overflow$
Accounting analysis of dynamic tables

Charge an amortized cost of $\hat{c}_i = 3$ for the $i$th insertion.
- $\$1$ pays for the immediate insertion.
- $\$2$ is stored for later table doubling.

When the table doubles, $\$1$ pays to move a recent item, and $\$1$ pays to move an old item.

**Example:**

<table>
<thead>
<tr>
<th>$i$</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
<th>8</th>
<th>9</th>
<th>10</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\text{size}_i$</td>
<td>1</td>
<td>2</td>
<td>4</td>
<td>8</td>
<td>8</td>
<td>8</td>
<td>16</td>
<td>16</td>
<td></td>
<td></td>
</tr>
<tr>
<td>$c_i$</td>
<td>1</td>
<td>2</td>
<td>3</td>
<td>1</td>
<td>5</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>9</td>
<td>1</td>
</tr>
<tr>
<td>$\hat{c}_i$</td>
<td>2</td>
<td>3</td>
<td>3</td>
<td>3</td>
<td>3</td>
<td>3</td>
<td>3</td>
<td>3</td>
<td>3</td>
<td>3</td>
</tr>
<tr>
<td>$\text{bank}_i$</td>
<td>1</td>
<td>2</td>
<td>2</td>
<td>4</td>
<td>2</td>
<td>4</td>
<td>6</td>
<td>8</td>
<td>2</td>
<td>4</td>
</tr>
</tbody>
</table>

*Okay, so I lied. The first operation costs only $\$2$, not $\$3$.

Accounting analysis (continued)

**Key invariant:** Bank balance never drops below 0. Thus, the sum of the amortized costs provides an upper bound on the sum of the true costs.

Incrementing a Binary Counter

**Given:** A $k$-bit binary counter $A[0,1,\ldots,k-1]$, initialized with $0,0,\ldots,0$. The counter supports the following INCREMENT operation:

```
INCREMENT(A) // increases counter by 1
i <- 0
while i < length(A) and A[i]=1 do
  A[i] <- 0
  i++
if i < length(A) then
  A[i] <- 1
```

**Question:** In a sequence of $n$ INCREMENT operations, what is the amortized runtime of one INCREMENT operation?
### Binary Counter Example

Example for $k=8$ and $n=9$:

<table>
<thead>
<tr>
<th></th>
<th>1→0 flip</th>
<th>0→1 flip</th>
</tr>
</thead>
<tbody>
<tr>
<td>Initial counter</td>
<td>0 0 0 0 0 0 0 0</td>
<td>$$1</td>
</tr>
<tr>
<td>After 1 increment</td>
<td>0 0 0 0 0 0 0 1</td>
<td>$$1</td>
</tr>
<tr>
<td>After 2 increments</td>
<td>0 0 0 0 0 0 1 0</td>
<td>$$1</td>
</tr>
<tr>
<td>After 3 increments</td>
<td>0 0 0 0 0 0 1 1</td>
<td>$$1</td>
</tr>
<tr>
<td>After 4 increments</td>
<td>0 0 0 0 0 1 0 0</td>
<td>$$2</td>
</tr>
<tr>
<td>After 5 increments</td>
<td>0 0 0 0 0 1 0 1</td>
<td>$$1</td>
</tr>
<tr>
<td>After 6 increments</td>
<td>0 0 0 0 1 0 0 0</td>
<td>$$3</td>
</tr>
<tr>
<td>After 7 increments</td>
<td>0 0 0 0 1 0 0 1</td>
<td>$$1</td>
</tr>
<tr>
<td>After 8 increments</td>
<td>0 0 0 1 0 0 0 0</td>
<td>$$1</td>
</tr>
<tr>
<td>After 9 increments</td>
<td>0 0 0 1 0 0 0 1</td>
<td>$$1</td>
</tr>
</tbody>
</table>

- The worst-case runtime of one INCREMENT operation is $O(k)$
- For $n$ operations the total is $O(nk)$

---

### Accounting Method

• Charge $\$2$ to set a bit to $1$ ($0\rightarrow1$ flip)
  - $\$1 pays for the actual flip
  - Store $\$1$ on the bit as credit to be used later when this bit is flipped back to $0$

• Charge $\$0$ to set a bit to $0$ ($1\rightarrow0$ flip)
  - Every $1$ in the counter has $\$1$ credit on it, which is used to pay for this flip

⇒ Since each INCREMENT operation is composed of one $0\rightarrow1$ flip and possibly multiple $1\rightarrow0$ flips, the asymptotic runtime of one INCREMENT operation is $O(1)$.
Conclusions

• Amortized costs can provide a clean abstraction of data-structure performance.
• Any of the analysis methods can be used when an amortized analysis is called for, but each method has some situations where it is arguably the simplest.
• Different schemes may work for assigning amortized costs in the accounting method, sometimes yielding radically different bounds.
