Single Source Shortest Paths

Paths in graphs

Consider a digraph $G = (V, E)$ with edge-weight function $w : E \rightarrow \mathbb{R}$. The **weight** of path $p = v_1 \rightarrow v_2 \rightarrow \dots \rightarrow v_k$ is defined to be

$$w(p) = \sum_{i=1}^{k-1} w(v_i, v_{i+1}).$$

Example:

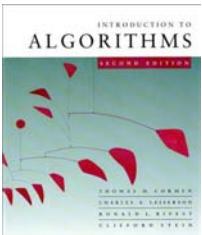

Shortest paths

A *shortest path* from u to v is a path of minimum weight from u to v . The *shortest-path weight* from u to v is defined as

$$\delta(u, v) = \min \{w(p) : p \text{ is a path from } u \text{ to } v\}.$$

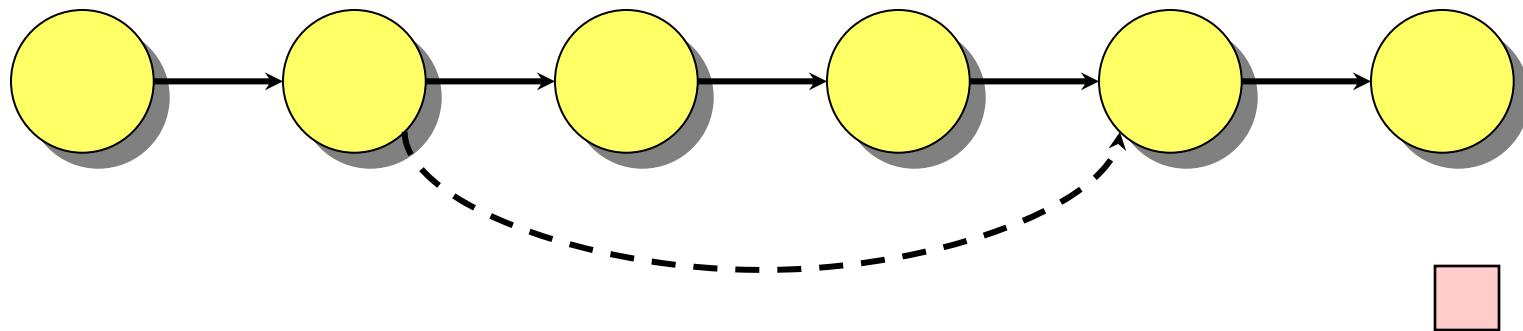

Note: $\delta(u, v) = \infty$ if no path from u to v exists.

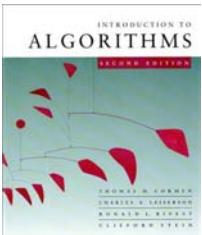

Optimal substructure

Theorem. A subpath of a shortest path is a shortest path.

Proof. Cut and paste:

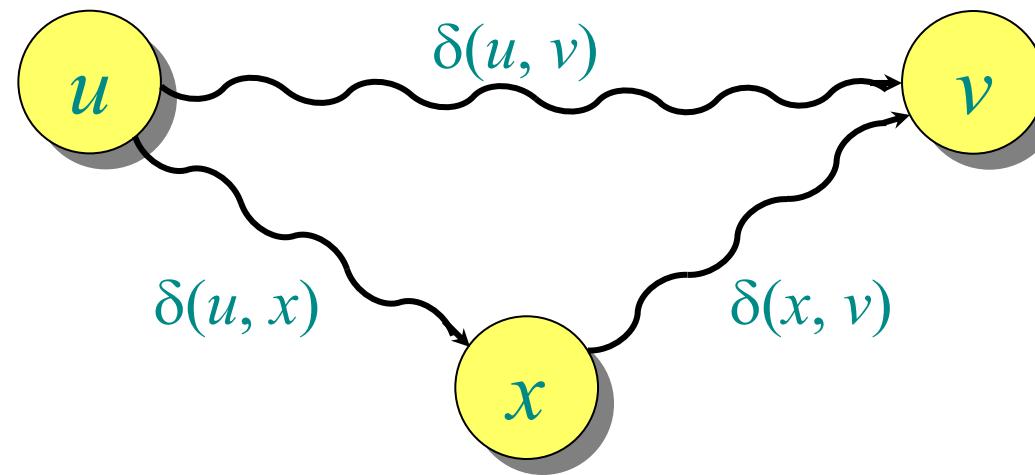

Triangle inequality

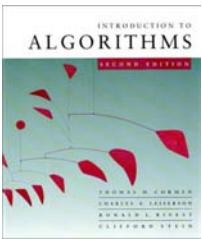

Theorem. For all $u, v, x \in V$, we have

$$\delta(u, v) \leq \delta(u, x) + \delta(x, v).$$

Proof.

- $\delta(u, v)$ minimizes over **all** paths from u to v
- Concatenating two shortest paths from u to x and from x to v yields **one** specific path from u to v

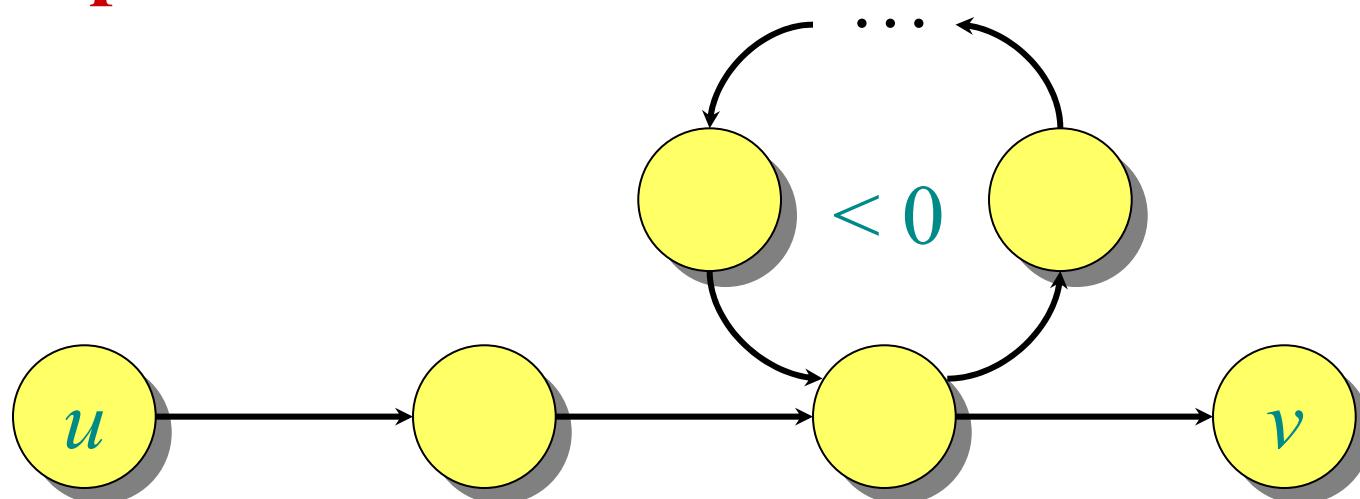

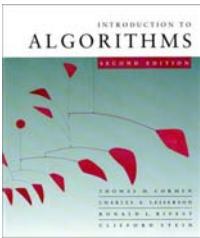

Well-definedness of shortest paths

If a graph G contains a negative-weight cycle, then some shortest paths may not exist.

Example:

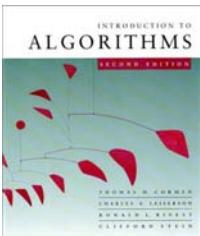

Single-source shortest paths

Problem. From a given source vertex $s \in V$, find the shortest-path weights $\delta(s, v)$ for all $v \in V$.

If all edge weights $w(u, v)$ are **nonnegative**, all shortest-path weights must exist.

IDEA: Greedy.

1. Maintain a set S of vertices whose shortest-path weights from s are known.
2. At each step add to S the vertex $v \in V - S$ whose distance estimate from s is minimal.
3. Update the distance estimates of vertices adjacent to v .

Dijkstra's algorithm

$d[s] \leftarrow 0$

for each $v \in V - \{s\}$
do $d[v] \leftarrow \infty$

$S \leftarrow \emptyset$

$Q \leftarrow V$ $\triangleright Q$ is a priority queue maintaining $V - S$

while $Q \neq \emptyset$ **do**

$u \leftarrow \text{EXTRACT-MIN}(Q)$

$S \leftarrow S \cup \{u\}$

for each $v \in \text{Adj}[u]$ **do**

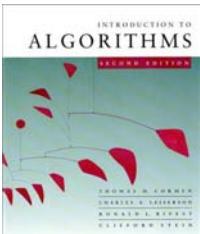

if $d[v] > d[u] + w(u, v)$ **then**

$d[v] \leftarrow d[u] + w(u, v)$

Dijkstra

```

 $d[s] \leftarrow 0$ 
for each  $v \in V - \{s\}$ 
    do  $d[v] \leftarrow \infty$ 
 $S \leftarrow \emptyset$ 
 $Q \leftarrow V$  ▷  $Q$  is a queue
while  $Q \neq \emptyset$  do

```

$u \leftarrow \text{EXTRACT-MIN}(Q)$

$$S \leftarrow S \cup \{u\}$$

for each $v \in \text{Adj}[u]$ do

if $d[v] > d[u] + w(u, v)$ **then**

$$d[v] \leftarrow d[u] + w(u, v)$$

PRIM's algorithm

$key[v] \leftarrow \infty$ for all $v \in V$

$\text{key}[s] \leftarrow 0$ for some arbitrary $s \in V$

while $Q \neq \emptyset$

do $u \leftarrow \text{EXTRACT-MIN}(Q)$

for each $v \in Adj[u]$

do if $v \in Q$ and $w(u, v) < key[v]$

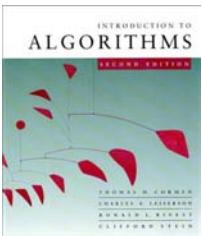

then $key[v] \leftarrow w(u, v)$

$\pi[v] \leftarrow u$

It suffices to only check $v \in Q$,
but it doesn't hurt to check all v

Correctness

Theorem. (i) For all $v \in S$: $d[v] = \delta(s, v)$
(ii) For all $v \notin S$: $d[v]$ = weight of shortest path from s to v that uses only (besides v itself) vertices in S .

Corollary. Dijkstra's algorithm terminates with $d[v] = \delta(s, v)$ for all $v \in V$.

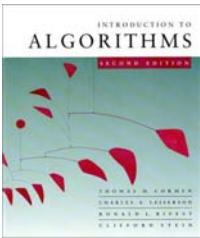

Correctness

Theorem. (i) For all $v \in S$: $d[v] = \delta(s, v)$
(ii) For all $v \notin S$: $d[v] = \text{weight of shortest path from } s \text{ to } v$ that uses only (besides v itself) vertices in S .

Proof. By induction.

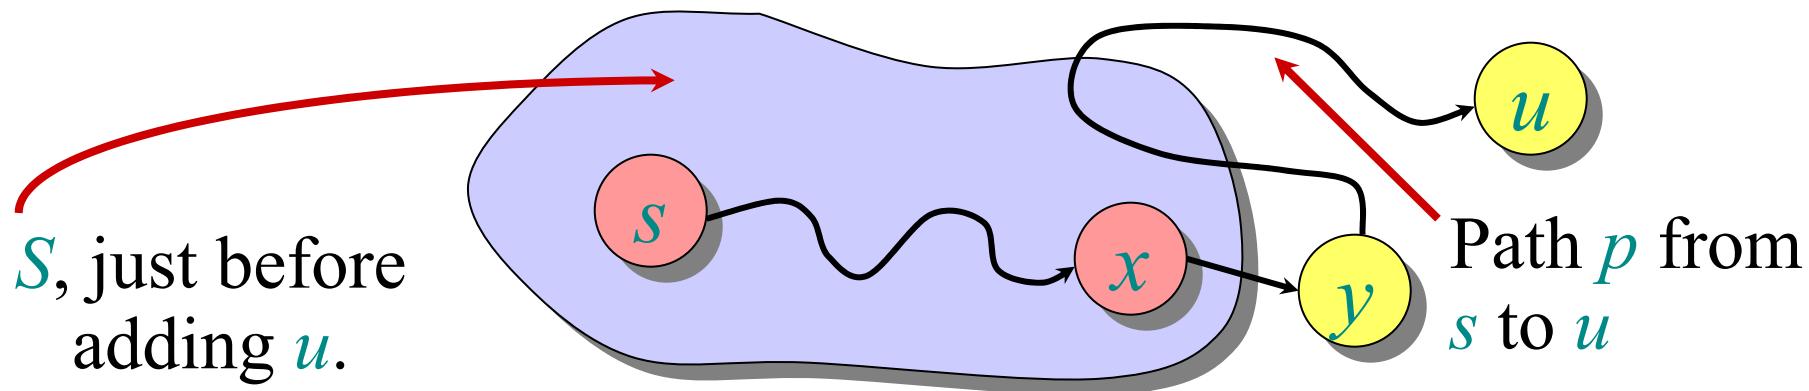

- Base: Before the while loop, $d[s]=0$ and $d[v]=\infty$ for all $v \neq s$, so (i) and (ii) are true.
- Step: Assume (i) and (ii) are true before an iteration; now we need to show they remain true after another iteration. Let u be the vertex added to S , so $d[u] \leq d[v]$ for all other $v \notin S$.

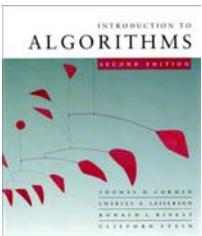

Correctness

Theorem. (i) For all $v \in S$: $d[v] = \delta(s, v)$
(ii) For all $v \notin S$: $d[v]$ = weight of shortest path from s to v that uses only (besides v itself) vertices in S .

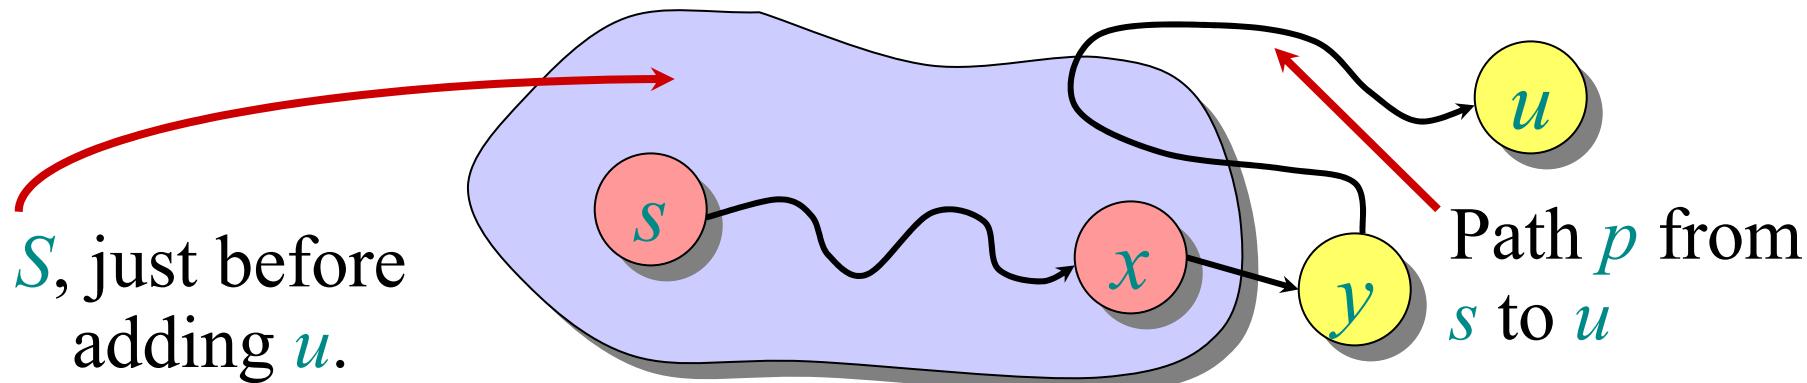

- (i) Need to show that $d[u] = \delta(s, u)$. Assume the contrary.
⇒ There is a path p from s to u with $w(p) < d[u]$. Because of (ii) that path uses vertices $\notin S$, in addition to u .
⇒ Let y be first vertex on p such that $y \notin S$.

Correctness

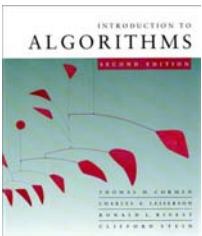

Theorem. (i) For all $v \in S$: $d[v] = \delta(s, v)$
(ii) For all $v \notin S$: $d[v]$ = weight of shortest path from s to v that uses only (besides v itself) vertices in S .

$\Rightarrow d[y] \leq w(p) < d[u]$. Contradiction to the choice of u .

weights are nonnegative

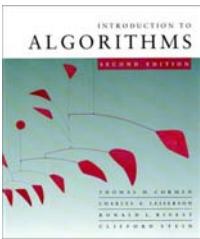

assumption about path

Correctness

Theorem. (i) For all $v \in S$: $d[v] = \delta(s, v)$
(ii) For all $v \notin S$: $d[v]$ = weight of shortest path from s to v that uses only (besides v itself) vertices in S .

- (ii) Let $v \notin S$. Let p be a shortest path from s to v that uses only (besides v itself) vertices in S .
 - p does not contain u : (ii) true by inductive hypothesis
 - p contains u : p consists of vertices in $S \setminus \{u\}$ and ends with an edge from u to v .
 $\Rightarrow w(p) = d[u] + w(u, v)$, which is the value of $d[v]$ after adding u . So (ii) is true.

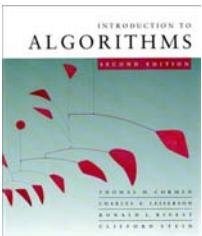

Unweighted graphs

Suppose $w(u, v) = 1$ for all $(u, v) \in E$. Can the code for Dijkstra be improved?

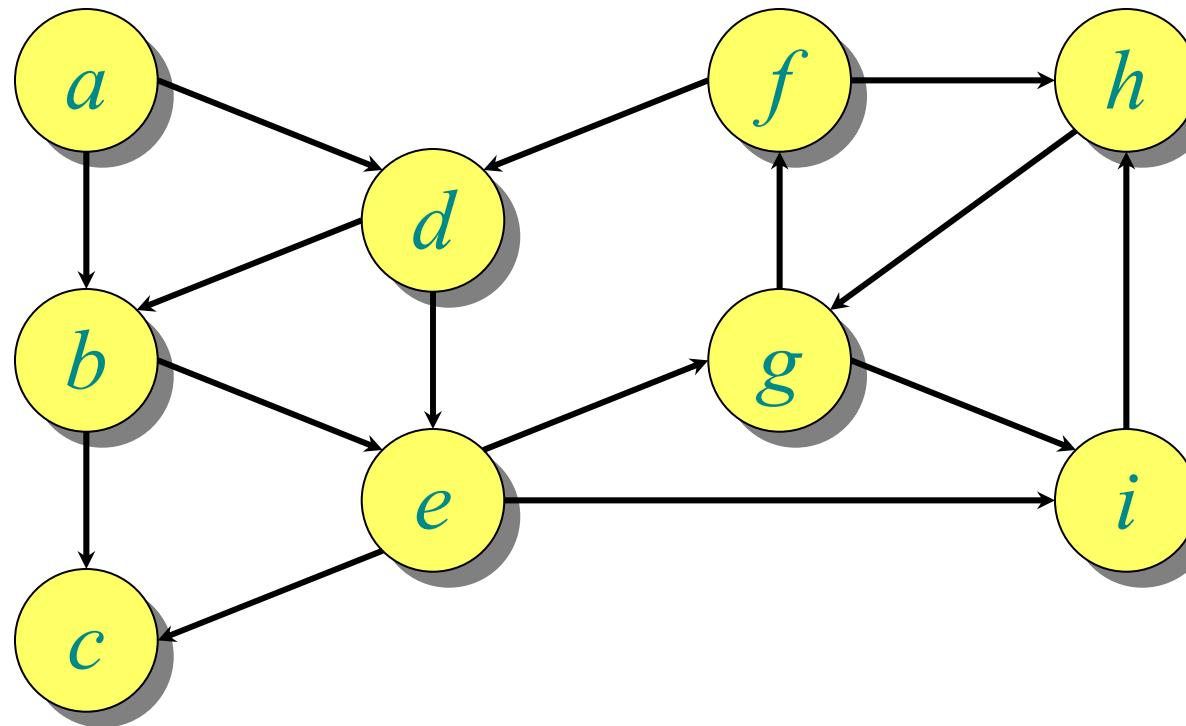

- Use a simple FIFO queue instead of a priority queue.
- **Breadth-first search**

```
while  $Q \neq \emptyset$ 
    do  $u \leftarrow \text{DEQUEUE}(Q)$ 
        for each  $v \in \text{Adj}[u]$ 
            do if  $d[v] = \infty$ 
                then  $d[v] \leftarrow d[u] + 1$ 
                    ENQUEUE( $Q, v$ )
```

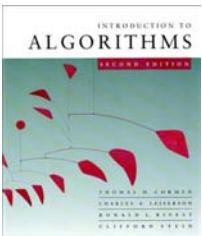

Analysis: Time = $O(|V| + |E|)$.

Correctness of BFS

```
while  $Q \neq \emptyset$ 
    do  $u \leftarrow \text{DEQUEUE}(Q)$ 
        for each  $v \in \text{Adj}[u]$ 
            do if  $d[v] = \infty$ 
                then  $d[v] \leftarrow d[u] + 1$ 
                    ENQUEUE( $Q, v$ )
```

Key idea:

The FIFO Q in breadth-first search mimics the priority queue Q in Dijkstra.

- **Invariant:** v comes after u in Q implies that $d[v] = d[u]$ or $d[v] = d[u] + 1$.

How to find the actual shortest paths?

Store a predecessor tree:

$d[s] \leftarrow 0$

$Q \leftarrow V$ $\triangleright Q$ is a priority queue maintaining $V - S$

while $Q \neq \emptyset$

do $u \leftarrow \text{EXTRACT-MIN}(Q)$

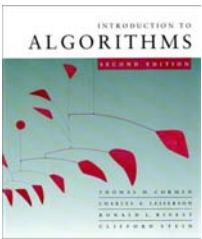

$S \leftarrow S \cup \{u\}$

for each $v \in \text{Adj}[u]$

do if $d[v] > d[u] + w(u, v)$
